#### BACKGROUND

- Infection is one of the most common complications in patients with nephrotic syndrome,
  especially in children.
- Infections: closely associated with frequent relapses and steroid dependency in NS →HIGH mortality, morbidity and health care costs, especially in developing countries
- Many different prophylactic interventions have been used or recommended for reducing the risks of infection in NS
- Prophylactic intervention can be recommended for routine use based on the current evidence is still unknown.

### **OBJECTIVE**

Assess benefits and harms of any prophylactic intervention for reducing the risk of infection in children and adults with nephrotic syndrome, regardless of cause or pathologic change.

#### Interventions for preventing infection in nephrotic syndrome (Review)

Wu HM, Tang JL, Cao L, Sha ZH, Li Y

#### **METHODS**

- All RCTs and quasi-RCTs looking at the benefits and harms of any prophylactic intervention (pharmacological or nonpharmacological) compared with placebo, no treatment or other pharmacological or non-pharmacological treatment were eligible for inclusion.
- Information was collected on methods, participants, interventions and outcomes
- Results were expressed as risk ratios (RR) for dichotomous outcomes or as mean differences (MD) for continuous data with 95% confidence intervals (CI).

#### SEARCH METHODS

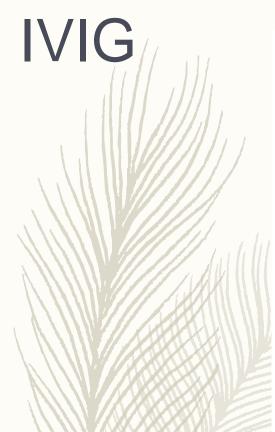

- The Cochrane Renal Group's specialised register
- The Cochrane Central Register of Controlled Trials (CENTRAL)
- MEDLINE and Pre-MEDLINE (from 1966), EMBASE (from 1980)
- China Biological Medicine Database (1979 to December 2009)
- Chinese Science and Technique Journals Database (to December 2009)
- China National Infrastructure (to December 2009)
- WangFang database (to December 2009)
- Reference lists of nephrology textbooks, review articles, relevant studies and abstracts from nephrology meetings without language restriction.
- Date of last search: 6 February 2012

Figure 1. Study flow diagram. Orginal number of records identified Records identified for current update: 186 through database searching: 367 Titles and abstracts screened: 553 Records excluded: 537 Original review: 367 Orginal review: 361 Update: 186 Update: 176 Full-text articles excluded: 4 Not relevant to preventing infection (2) Full-text articles assessed for eligibility: 16 Mixed population, unable to Original review: 6 separate data (1) Update: 10 Not randomised (1) Included studies: 12 Original review: 5 Review update: 7

#### RESULTS

- Twelve studies 762 children with NS
- All from China, no other countries
- All studies compared one kind of prophylactic pharmacotherapy: IVIG, thymosin, oral transfer factor, mannan peptide tablet, BCG vaccine, polyvalent bacterial vaccine (Lantigen B) and two kinds of Chinese medicinal herbs plus baseline treatment with baseline treatment alone
- No RCTs were identified comparing antibiotics, non-pharmacological prophylaxis, or pneumococcal vaccination

#### Analysis I.I. Comparison I IVIG + baseline treatment versus baseline treatment, Outcome I Number of patients developing infection.

#### RESULTS

- Thymosin: 1 study, 40 participants (Zhang 2000) reduced the risk of infection in children with NS(RR 0.50, 95% CI 0.26 to 0.97).
- BCG vaccine injection 1 study, 38 participants (Kang 2003) prevented secondary infection in children with NS (RR 0.68, 95% CI 0.48 to 0.95)
- Mannan peptide: 1 study, 67 participants (Guo 2008) not superior to the control for preventing secondary infections in children with NS (RR 0.46, 95% CI 0.21 to 1.01)
- Oral transfer factor: 1 study, 98 participants (Rao 2005) reduced the risk of infection in children with simple NS (RR 0.51, 95% CI 0.35 to 0.73)

#### CONCLUSIONS

- Compared with control, IVIG, thymosin, oral transfer factor, BCG vaccine injection, Huangqi granules, and TIAOJINING may have positive effects on the prevention of nosocomial infection or unspecified infection
- Mannan peptide and polyvalent bacterial vaccine were not superior to control on the prevention
- No studies were identified that used chemoprophylaxis, pneumococcal vaccination, varicella vaccine or any other non- pharmacological interventions for reducing the risk of infection in children or adults with nephrotic syndrome.
- The methodological quality of all studies was poor, the sample sizes small, and all studies were from China→ NO STRONG EVIDENCE on the effectiveness of these interventions.
